physicochemical features. This invention also relates  
10 to pharmaceutical compositions comprising these

### BACKGROUND OF THE INVENTION

The human immunodeficiency virus ("HIV") is the causative agent for acquired immunodeficiency syndrome ("AIDS") -- a disease characterized by the destruction of the immune system, particularly of CD4<sup>+</sup> T-cells, with attendant susceptibility to opportunistic infections -- and its precursor AIDS-related complex ("ARC") -- a syndrome characterized by symptoms such as persistent generalized lymphadenopathy, fever and weight loss.

As in the case of several other retroviruses, HIV encodes the production of a protease which carries out post-translational cleavage of precursor polypeptides in a process necessary for the formation of infectious virions (S. Crawford et al., "A Deletion Mutation in the 5' Part of the pol Gene of Moloney Murine Leukemia Virus Blocks Proteolytic Processing of the gag and pol Polyproteins", J. Virol., 53, p. 899 (1985)). These gene products include pol, which encodes the virion RNA-dependent DNA polymerase (reverse transcriptase), an endonuclease, HIV protease, and gag, which encodes the core-proteins of the virion (H. Toh et al., "Close Structural Resemblance Between Putative Polymerase of a Drosophila Transposable Genetic Element 17.6 and pol gene product of Moloney Murine Leukemia Virus", EMBO J., 4, p. 1267 (1985); L.H. Pearl et al., "A Structural Model for the Retroviral Proteases", Nature, pp. 329-351 (1987); M.D. Power et al., "Nucleotide Sequence of SRV-1, a Type D Simian Acquired Immune Deficiency Syndrome Retrovirus", Science, 231, p. 1567 (1986)).

A number of synthetic anti-viral agents have been designed to target various stages in the

- 3 -

replication cycle of HIV. These agents include compounds which block viral binding to CD4<sup>+</sup> T-lymphocytes (for example, soluble CD4), and compounds which interfere with viral replication by inhibiting viral reverse transcriptase (for example, didanosine and zidovudine (AZT)) and inhibit integration of viral DNA into cellular DNA (M.S. Hirsh and R.T. D'Aquila, "Therapy for Human Immunodeficiency Virus Infection", N.Eng.J.Med., 328, p. 1686 (1993)). However, such agents, which are directed primarily to early stages of viral replication, do not prevent the production of infectious virions in chronically infected cells. Furthermore, administration of some of these agents in effective amounts has led to cell-toxicity and unwanted side effects, such as anemia and bone marrow suppression.

More recently, drug design efforts have been directed toward creating compounds which inhibit the formation of infectious virions by interfering with the processing of viral polyprotein precursors. Processing of these precursor proteins requires the action of virus-encoded proteases which are essential for replication (Kohl, N.E. et al. "Active HIV Protease is Required for Viral Infectivity" Proc. Natl. Acad. Sci. USA, 85, p. 4686 (1988)). The anti-viral potential of HIV protease inhibition has been demonstrated using peptidal inhibitors. Such peptidal compounds, however, are typically large and complex molecules that tend to exhibit poor bioavailability and are not generally consistent with oral administration. Accordingly, the need still exists for compounds that can effectively inhibit the action of viral proteases, for use as agents for preventing and treating chronic and acute viral infections. Such agents would be expected to act

- 4 -

as effective therapeutic agents in their own right. In addition, since they act at a separate stage in the virus life cycle from previously described antiretroviral agents, the administration of a  
5 combination of agents would be expected to result in increased therapeutic efficacy.

#### SUMMARY OF THE INVENTION

The present invention provides a novel class  
10 of compounds, and pharmaceutically acceptable derivatives thereof, that are useful as inhibitors of aspartyl proteases, and in particular, HIV aspartyl protease. The compounds of this invention can be used alone or in combination with other therapeutic or

The term "protecting group" refers to a  
suitable chemical group which may be attached to a  
functional group and removed at a later stage to reveal  
the intact functional group. Examples of suitable  
35 protecting groups for various functional groups are

- 15 -

described in T.W. Greene and P.G.M. Wuts, Protective Groups in Organic Synthesis, 2d. Ed., John Wiley and Sons (1991); L. Fieser and M. Fieser, Fieser and Fieser's Reagents for Organic Synthesis, John Wiley and Sons (1994); L. Paquette, ed. Encyclopedia of Reagents for Organic Synthesis, John Wiley and Sons (1995).

The term "fused" whether preceded by the term "optionally" or not, refers to a structure wherein two distinct ring systems are joined together such that both rings share at least two common atoms. This can be envisioned as the replacement of a carbon-hydrogen or nitrogen-hydrogen bond on a ring atom with a carbon-carbon (from a second ring) or nitrogen-carbon (from a second ring) bond. For example, a cyclohexyl ring fused to a second cyclohexyl ring results in a decahydronaphthalene, a cyclohexyl ring fused to a piperidine ring results in a decahydroquinoline or decahydroisoquinoline, or a phenyl ring fused to a thiazole ring results in a benzothiazole.

The term "substituted", whether preceded by the term "optionally" or not, and substitutions contained in formulas of this invention, refer to the replacement of one or more hydrogen radicals in a given structure with the radical of a specified substituent. When more than one position in a given structure may be substituted with more than one substituent selected from a specified group, the substituents may be either the same or different at every position (for example, the moiety  $-N(R^2)(R^2)$ ). Typically, when a structure may be optionally substituted, 0-3 substitutions are preferred, and 0-1 substitutions is more preferred. Most preferred substituents are those which enhance protease inhibitory activity or intracellular antiviral activity in permissive mammalian cells or immortalized mammalian cell lines, or which enhance deliverability

- 16 -

by enhancing solubility characteristics or enhancing pharmacokinetic or pharmacodynamic profiles as compared to the unsubstituted compound. Other more preferred substituents include those used in the compounds shown in Tables 1-5.

5           The term "pharmaceutically effective amount" refers to an amount effective in treating HIV infection in a patient either as monotherapy or in combination with other agents. The term "treating" as used herein  
10       refers to the alleviation of symptoms of a particular disorder in a patient or the improvement of an ascertainable measurement associated with a particular disorder. Specifically, with respect to HIV, effective  
15       treatment using the compounds and compositions of this invention would result in an improvement in an HIV associated ascertainable measurement. The term  
"prophylactically effective amount" refers to an amount effective in preventing HIV infection in a patient. As  
20       used herein, the term "patient" refers to a mammal, including a human.

          The term "pharmaceutically acceptable carrier or adjuvant" refers to a carrier or adjuvant that may be administered to a patient, together with a compound of this invention, and which does not destroy the  
25       pharmacological activity thereof and is nontoxic when administered in doses sufficient to deliver a therapeutic amount of the antiretroviral agent.

          As used herein, the compounds of this invention, including the compounds of formula I are  
30       defined to include pharmaceutically acceptable derivatives or prodrugs thereof. A "pharmaceutically acceptable derivative or prodrug" means any pharmaceutically acceptable salt, ester, salt of an ester, or other derivative of a compound of this

- 17 -

invention which, upon administration to a recipient, is capable of providing (directly or indirectly) a compound of this invention or an inhibitorily active metabolite or residue thereof. Particularly favored derivatives and prodrugs are those that increase the bioavailability of the compounds of this invention when such compounds are administered to a mammal (e.g., by allowing an orally administered compound to be more readily absorbed into the blood) or which enhance delivery of the parent compound to a biological compartment (e.g., the brain or lymphatic system) relative to the parent species.

Pharmaceutically acceptable salts of the compounds of this invention include those derived from pharmaceutically acceptable inorganic and organic acids and bases. Examples of suitable acids include hydrochloric, hydrobromic, sulfuric, nitric, perchloric, fumaric, maleic, phosphoric, glycollic, lactic, salicylic, succinic, toluene-p-sulfonic, tartaric, acetic, citric, methanesulfonic, ethanesulfonic, formic, benzoic, malonic, naphthalene-2-sulfonic and benzenesulfonic acids. Other acids, such as oxalic, while not in themselves pharmaceutically acceptable, may be employed in the preparation of salts useful as intermediates in obtaining the compounds of the invention and their pharmaceutically acceptable acid addition salts.

Salts derived from appropriate bases include alkali metal (e.g., sodium), alkaline earth metal (e.g., magnesium), ammonium and  $N-(C_{1-4} \text{ alkyl})_4^+$  salts.

The term "thiocarbamates" refers to compounds containing the functional group  $N-SO_2-O$ .

The compounds of this invention contain one or more asymmetric carbon atoms and thus occur as

- 18 -

racemates and racemic mixtures, single enantiomers, diastereomeric mixtures and individual diastereomers. All such isomeric forms of these compounds are expressly included in the present invention. Each  
5 stereogenic carbon may be of the R or S configuration. Although the specific compounds exemplified in this application may be depicted in a particular stereochemical configuration, compounds having either the opposite stereochemistry at any given chiral center  
10 or mixtures thereof are also envisioned.

Combinations of substituents and variables envisioned by this invention are only those that result in the formation of stable compounds. The term "stable", as used herein, refers to compounds which  
15 possess stability sufficient to allow manufacture and which maintains the integrity of the compound for a sufficient period of time to be useful for the purposes detailed herein (e.g., therapeutic or prophylactic administration to a mammal or for use in affinity  
20 chromatography applications). Typically, such compounds are stable at a temperature of 40°C or less, in the absence of moisture or other chemically reactive conditions, for at least a week.

The compounds of the present invention may be  
25 used in the form of salts derived from inorganic or organic acids. Included among such acid salts, for example, are the following: acetate, adipate, alginate, aspartate, benzoate, benzenesulfonate, bisulfate, butyrate, citrate, camphorate, camph-  
30 orsulfonate, cyclopentanepropionate, digluconate, dodecylsulfate, ethanesulfonate, fumarate, glucohepta-  
noate, glycerophosphate, hemisulfate, heptanoate, hexa-  
noate, hydrochloride, hydrobromide, hydroiodide, 2-  
hydroxyethanesulfonate, lactate, maleate,

- 19 -

methanesulfonate, 2-naphthalenesulfonate, nicotinate,  
oxalate, pamoate, pectinate, persulfate, 3-  
phenylpropionate, picrate, pivalate, propionate,  
succinate, tartrate, thiocyanate, tosylate and  
5 undecanoate.

This invention also envisions the  
quaternization of any basic nitrogen-containing groups  
of the compounds disclosed herein. The basic nitrogen  
can be quaternized with any agents known to those of  
10 ordinary skill in the art including, for example, lower  
alkyl halides, such as methyl, ethyl, propyl and butyl  
chloride, bromides and iodides; dialkyl sulfates  
including dimethyl, diethyl, dibutyl and diamyl  
sulfates; long chain halides such as decyl, lauryl,  
15 myristyl and stearyl chlorides, bromides and iodides;  
and aralkyl halides including benzyl and phenethyl  
bromides. Water or oil-soluble or dispersible products  
may be obtained by such quaternization.

In an alternate embodiment, this invention also relates to novel methods for preparing compounds and intermediates of the following structures.

One embodiment relates to a process

The compounds of this invention may be synthesized using conventional techniques. Advantageously, these compounds are conveniently synthesized from readily available starting materials.

Although the syntheses of the compounds of this invention are known to those of skill in the art, the following general schemes are set forth to illustrate these methods. These schemes should not be viewed as limiting the scope of this invention in any way.

Using standard techniques, compounds of the present invention having the general formula I may be obtained as described in the following schemes:

Methods for producing the compounds of this invention are well known in the art of organic synthesis. Several intermediates are commercially available, e.g. from Aldrich Chemical Company, Inc., Milwaukee, WI. The synthesis of heterocycles E1-E6 (Schemes 1 and 2) begins with any protected amino aldehyde, the preparations for which are well known in the art from suitably protected amino acids, esters or alcohols. In the case of the this intermediate, transient protection of the amino group may be accomplished by means known in the art (see, e.g. T.W. Greene and P.G.M. Wuts "Protective Groups in Organic Synthesis", Second Edition, pp. 309-405 ©1991 John Wiley and Sons, Inc. New York, NY and E. Gross and J.

- 110 -

Meinhofer "The Peptides, Vol. 3: Protection of Functional Groups in Peptide Synthesis" pp. 3-88; ©1981 Academic Press, Inc. New York, NY). Carbamates such as Boc, Fmoc, Alloc and Cbz are particularly convenient protecting groups, the introduction and removal of are described in the above references.

The synthesis of E1 is illustrated in Scheme 1. The protected amino aldehyde is treated with an alpha substituted or alpha, alpha disubstituted amino ester under typical reductive amination conditions well known in the art, such as sodium cyanoborohydride in a solvent mixture of DMF/Acetic acid. The resulting compound EI is then deprotected and free based with either a tertiary amine base or potassium carbonate in methanol to effect cyclization to form EII. The resulting secondary amine may then be protected with groups (detailed in the references above) such as benzyl or t-butyloxycarbonyl (Boc) utilizing conditions well known in the art to form analogs of E1.

Preparation of E2 is achieved by reaction of a starting aldehyde with ethyl diethylphosphoranylmethanesulfonate and subsequent reduction of the double bond (see: Gennari et al., Angew. Chem. Int. Ed. Engl., 33, pp. 2067-69 (1994)) to yield compound EIIIa. Cyclization may then be achieved by deesterification and activation of the sulfonate moiety as described in Gennari, followed by deprotection of the nitrogen protection group to yield the cyclized product EIV. Alternatively, an amino acid may be converted to compound EIIIb using standard synthetic methods illustrated in Scheme 1. Compound EIIIb can be cyclized to afford compound EIV. Compound EIV may then be N-protected, for example, in the presence of Boc anhydride and DMAP (see: Flynn et al.,

- 111 -

J. Org. Chem. 48, pp. 2424-26 (1983)), and treated with a non-nucleophilic base such as LDA or hexamethyldisilazane to generate the anion at the center alpha to the SO<sub>2</sub> moiety. This anion may then be quenched with a variety of electrophiles and subsequently deprotected to form the desired analogs of E2. Alternatively, this anion may be quenched with an aldehyde to form (after subsequent dehydration, i.e., an aldol-type condensation) an exo-methylene compound which may then be reduced (i.e., hydrogenation) to form the desired analogs of E2. Analogously, preparation of E3 results from a Wittig reaction using methyl(triphenylphosphoranylidene) acetate followed by simultaneous reduction of the double bond and cyclization using magnesium metal in methanol (Wei et al., Tetrahedron Lett., 34(28), pp. 4439-42 (1993)). A similar N-protection, deprotonation, quench and N-deprotection scheme, or condensation-reduction scheme, as described in the preparation of E2, results in desired analogs of E3. Alternatively, E3 may be prepared from commercially available EVI. The hydroxyl group may be activated using commonly available reagents such as methanesulfonyl chloride or para-toluenesulfonyl chloride in the presence of a tertiary amine base. The addition of a nucleophile to displace the mesylate or tosylate yields EVII (Ackermann et al., Helv. Chim. Acta, 73, pp. 122-32 (1990)) which may be treated as described above to obtain E3.

Methods for the preparation of compounds E4-E6 are also well known in the art and stem from readily available protected amino aldehydes. Treatment of these aldehydes with a variety of amines under reductive amination conditions well known in the art, such as sodium cyanoborohydride using DMF/Acetic acid

- 112 -

as a solvent mixture, followed by deprotection of the primary amine yields diamine EVIII. Intramolecular cyclization with a variety of activated carbonyl, dicarbonyl or sulfuryl equivalents in the presence of a tertiary amine base yields compounds E4-E6. Examples of activating reagents include but are not limited to carbonyldiimidazole, phosgene, sulfuryldichloride, sulfuryldiimidazole, sulfonyl diimide, and oxalyl chloride.

Methods leading to the production of analogs of compound E7 are also known in the art (McManus et al., J. Med. Chem., 8, pp. 766-76 (1965)). Scheme 3 exemplifies several potential routes to the synthesis of compound E7. Any protected amino alcohol may be deprotonated to form the alkoxide which may be reacted with a substituted alpha bromo ester to form ether EIX (route A). Alternatively (route B), EIX may be formed from activation of a protected amino alcohol with, for example, methanesulfonyl chloride or para-toluenesulfonyl chloride in the presence on a tertiary amine base and subsequent addition of a nucleophile such as an alkoxide from an alpha hydroxy acid to displace mesylate or tosylate to yield EIX. Compound EIX can then be deprotected, free based with a tertiary amine base or potassium carbonate in methanol, and heated to effect cyclization to form E7. Alternatively (route C), E7 may be prepared from a protected amino alcohol by protection of the hydroxyl group with, for example, t-butyldimethyl silyl chloride/imidazole to afford the silyl ether. Subsequent nitrogen deprotection and acylation with a alpha bromo acid in the presence of any number of available coupling agents (for example dicyclohexylcarbodiimide, other related carbodiimide reagents or isobutyl chloroformate) or

- 113 -

acylation with an alpha bromo acid chloride provides compound EX. Desilylation using, for example, tetrabutylammonium formate in THF followed by formation of the alkoxide with base affords cyclization to E7.

5 Alternatively, E7 may be prepared from the corresponding  $\alpha$ -methylene compound (i.e., both  $R^2$  are H in E7, the nitrogen may be protected if necessary) by a multiple deprotonation-alkylation sequence to give an E7 wherein each  $R^2$  is inserted in an independent  
10 alkylation step and each  $R^2$  may be attached to form a spirocyclic product (i.e., alkylation with a dihaloalkane).

Schemes 4-6 describe methods for converting the cyclic compounds E1-E7 into compounds of this  
15 invention. For example, compounds of the type Z, exemplified by compounds E1-E7, may be deprotonated and reacted with a functionalized epoxide to generate the desired compounds as described in Scheme 4. Several of the described epoxides are readily  
20 synthesized via methods well known in the art (Maligres et al., Tetrahedron Lett., 36, pp. 2195-98 (1995)). Optionally, further modification of the compounds may be performed subsequent to epoxide opening using reactions and materials well known in the art. For  
25 example, subsequent to epoxide opening utilizing example EXIb deprotection of the carbamate allows further modification of the unmasked amine.

Alternatively, as shown in Scheme 5, compounds EZ may be converted to the desired products  
30 in a more stepwise fashion. Compounds EZ may be deprotonated using, for example, sodium hydride in DMF and treated with a three carbon based epoxide to generate epoxide EXII. Examples of such reagents include, but are not limited to, epibromohydrin,

- 114 -

epichlorohydrin and glycidyl tosylate. Several other potential methods for preparing compounds of the type EXII are well known in the art, for example, the anion of Z may be reacted with allyl bromide or allyl iodide to form an allyl intermediate, which may subsequently be oxidized to form the desired epoxide. Several epoxidation conditions for the generation of either racemic or chiral epoxides are well known in the art. Epoxide EXII may then be treated with an amine and subsequently carbonylated or sulfonated using activated species well known in the art to generate final compounds of the type E9. Alternatively EXII may be reacted with a functionalized secondary amine followed by optional manipulation of  $R^2$  to produce compounds of the type E10. One example of such manipulation is reaction of EXII with the known Boc piperazine EXIII (Dorsey et al., J. Med. Chem., 37, pp. 3443-51 (1994)). Subsequent to epoxide opening, the Boc group may be removed and the unmasked secondary amine may be further manipulated by reaction with various electrophiles to form the desired product.

Scheme 6 describes a method for introduction of electrophiles into compounds of the type EXIV. Said compounds may be protected with a variety of protecting groups, for example t-butyldimethylsilyl triflate, to mask the secondary hydroxyl group followed by treatment with a non-nucleophilic base such as lithium diisopropylamide or hexamethyldisilylamine to generate the anion alpha to the carbonyl. Various electrophiles may then be added to substitute the position alpha to the carbonyl, or alternatively an aldol-type condensation-reduction scheme may be employed. Deprotection of the secondary hydroxyl then yields the desired product.

- 115 -

As can be appreciated by the skilled artisan, the above synthetic schemes are not intended to comprise a comprehensive list of all means by which the compounds described and claimed in this application may be synthesized. Further methods will be evident to those of ordinary skill in the art.

Moreover, the determination of the optimum overall scheme, as well as the choice of reagents and reactions used to carry out the various steps in a given scheme will be based upon factors that are readily apparent to those of skill in the art. These factors include the identity of the compound to be produced, the efficiency of the individual steps and schemes in producing that compound in terms of overall yield, time, and cost and availability of reagents. It will therefore be apparent that some routine experimentation may be required in determining the optimum scheme to produce certain compounds of this invention.

It should be understood that the compounds of this invention may be modified by appending appropriate functionalities to enhance selective biological properties. Such modifications are known in the art and include those which increase biological penetration into a given biological compartment (e.g., blood, lymphatic system, central nervous system), increase oral availability, increase solubility to allow administration by injection, alter metabolism and alter rate of excretion.

The compounds of this invention are characterized by a superior ability to inhibit protease activity and viral replication, particularly aspartyl protease activity. These compounds are especially well suited for inhibiting HIV aspartyl protease. We

- 116 -

believe that this activity is due to specific steric and electronic interactions between the protease and compounds of this invention. This belief stems from our analysis of the structural basis for the activity of compounds of this invention, in view of the known crystal structures of HIV protease and bound inhibitors, such as the structure reported in Miller et al. "Structure of Complex of Synthetic HIV-1 Protease with a Substrate-Based Inhibitor at 2.3 Å Resolution", Science, vol. 246, pp. 1149-1152 (1989), which is incorporated herein by reference, as well as structures determined in our laboratories.

The novel compounds of the present invention are excellent ligands for aspartyl proteases, particularly HIV-1 and HIV-2 proteases. Accordingly, these compounds are capable of targeting and inhibiting late stage events in HIV replication, i.e., the processing of the viral polyproteins by HIV encoded proteases. Such compounds inhibit the proteolytic processing of viral polyprotein precursors by inhibiting aspartyl protease. Because aspartyl protease is essential for the production of mature virions, inhibition of that processing effectively blocks the spread of virus by inhibiting the production of infectious virions, particularly from chronically infected cells. Compounds according to this invention advantageously inhibit the ability of the HIV-1 virus to infect immortalized human T cells over a period of days, as determined by an assay of extracellular p24 antigen -- a specific marker of viral replication. Other anti-viral assays have confirmed the potency of these compounds.

The compounds of this invention may be employed in a conventional manner for the treatment of

- 117 -

viruses, such as HIV and HTLV, which depend on aspartyl proteases for obligatory events in their life cycle. Such methods of treatment, their dosage levels and requirements may be selected by those of ordinary skill in the art from available methods and techniques. For example, a compound of this invention may be combined with a pharmaceutically acceptable adjuvant for administration to a virally-infected patient in a pharmaceutically acceptable manner and in an amount effective to lessen the severity of the viral infection or to alleviate pathological effects associated with HIV infection or immunosuppression such as opportunistic infections or various cancers, tumors, CMV retinitis, candida infections, maternal fetal transmission, and AIDS related dementia,.

Alternatively, the compounds of this invention may be used in prophylactics and methods for protecting individuals against viral infection during a specific event, such as childbirth, or over an extended period of time. The compounds may be employed in such prophylactics either alone or together with other antiretroviral agents to enhance the efficacy of each agent. As such, the novel protease inhibitors of this invention can be administered as agents for treating or preventing HIV infection in a mammal.

The compounds of formula I, especially those having a molecular weight of less than about 700 g/mole, may be readily absorbed into the bloodstream of mammals upon oral administration. Compounds of formula I having a molecular weight of less than about 600 g/mole and aqueous solubility of greater than or equal to 0.1 mg/mL are most likely to demonstrate high and consistent oral availability. This surprisingly impressive oral availability makes such compounds

- 118 -

excellent agents for orally-administered treatment and prevention regimens against HIV infection.

The compounds of this invention may be administered to a healthy or HIV-infected patient either as a single agent or in combination with other anti-viral agents which interfere with the replication cycle of HIV. By administering the compounds of this invention with other anti-viral agents which target different events in the viral life cycle and which target different viral substrains with varying susceptibility to specific agents, the therapeutic effect of these compounds is potentiated. For instance, the co-administered anti-viral agent can be one which targets early events in the life cycle of the virus, such as cell entry, reverse transcription and viral DNA integration into cellular DNA. Anti-HIV agents targeting such early life cycle events include, didanosine (ddI), dideoxycytidine (ddC), d4T, zidovudine (AZT), 3TC, 935U83, 1592U89, 524W91, polysulfated polysaccharides, sT4 (soluble CD4), ganciclovir, trisodium phosphonoformate, eflornithine, ribavirin, acyclovir, alpha interferon and trimethotrexate. Additionally, non-nucleoside inhibitors of reverse transcriptase, delavirdine (U90) or nevirapine, may be used to potentiate the effect of the compounds of this invention, as may viral uncoating inhibitors, inhibitors of trans-activating proteins such as tat or rev, or inhibitors of the viral integrase.

Combination therapies according to this invention exert an additive or synergistic effect in inhibiting HIV replication because each component agent of the combination acts on a different site of HIV replication or on different strains of virus present in

- 119 -

an infectious population. The use of such combination therapies may also advantageously reduce the dosage of a given conventional anti-retroviral agent which would be required for a desired therapeutic or prophylactic effect, as compared to when that agent is administered as a monotherapy. Such combinations may reduce or eliminate the side effects of conventional single anti-retroviral agent therapies, while not interfering with the anti-retroviral activity of those agents. These combinations reduce potential of resistance to single agent therapies, while minimizing any associated toxicity.

Advantages of combining HIV protease inhibitors may include viral population effects, whereby certain members of a virus population which show reduced sensitivity to one protease inhibitor may be fully sensitive to another inhibitor or may in fact have enhanced sensitivity to the second inhibitor. Alternatively or in addition, administration of two or more different inhibitors may be used to reduce specific toxicities associated with a single agent. This advantage of combination therapy also applies to, co-administration of the protease inhibitor of this invention with other antiviral agents. Alternatively or in addition, co-administration of more than one protease inhibitor may lower the rate of metabolic inactivation of the compounds of this invention, for instance, by inhibiting enzymatic systems such as cytochrome P<sub>450</sub>, or esterases or the like. In particular, co-administration of compounds of this invention with protease inhibitors such as ritonavir or other agents such as ketoconazole, grapefruit juice and antiulcer medications such as H<sub>2</sub>-blockers, which

- 120 -

inhibits cytochrome P<sub>450</sub> 3A<sub>4</sub>, may advantageously enhance their biological half-life.

These combinations may also increase the efficacy of the conventional agent without increasing the associated toxicity. Compounds of this invention in combination with other anti-HIV agents may act in an additive or synergistical manner in preventing the replication of HIV in human T cells. Preferred combination therapies include the administration of a compound of this invention with AZT, ddI, ddC, d4T, 3TC, 935U83, 1592U89, 524W91 or a combination thereof.

Alternatively, the compounds of this invention may also be co-administered with other HIV protease inhibitors such as VX-478 (Vertex, also known as 141W94 (Glaxo-Wellcome) and K VX-478 (Kissei)), saquinavir (Ro 31-8959, Roche), indinavir (L-735,524, Merck)), ritonavir (ABT 538, Abbott), nelfinavir (AG 1343, Agouron), palinavir (Bila 2011 BS), U-103017 (Upjohn), XM 412 (DuPont Merck), XM 450 (DuPont Merck), BMS 186318 (Bristol-Meyers Squibb), CPG 53,437 (Ciba Geigy), CPG 61,755 (Ciba Geigy), CPG 70,726 (Ciba Geigy), ABT 378 (Abbott), GS 3333 (Gilead Sciences), GS 3403 (Gilead Sciences), GS 4023 (Gilead Sciences), GS 4035 (Gilead Sciences), GS 4145 (Gilead Sciences), GS 4234 (Gilead Sciences), and GS 4263 (Gilead Sciences) or prodrugs of these or related compounds to increase the effect of therapy or prophylaxis against various viral mutants or members of HIV quasi species.

We prefer administering the compounds of this invention as single agents or in combination with retroviral reverse transcriptase inhibitors, such as nucleoside derivatives, or other HIV aspartyl protease inhibitors, including multiple combinations comprising from 3-5 agents. We believe that the co-administration

- 121 -

of the compounds of this invention with retroviral reverse transcriptase inhibitors or HIV aspartyl protease inhibitors may exert a substantial additive or synergistic effect, thereby preventing, substantially reducing, or completely eliminating viral replication or infection or both, and symptoms associated therewith. Particularly preferred is administration of a combination of a compound of formula I, 3TC and zidovudine (AZT). Also preferred are administrations of combinations of a compound of formula I and 1592U89, or of compounds of formula I with VX-478, optionally with one or more reverse transcriptase inhibitors, particularly, AZT, 3TC and 1592U89.

The compounds of this invention can also be administered in combination with immunomodulators and immunostimulators (e.g., bropirimine, anti-human alpha interferon antibody, IL-2, GM-CSF, interferon alpha, diethyldithiocarbamate, tumor necrosis factor, naltrexone, tuscarasol, and rEPO); and antibiotics (e.g., pentamidine isethionate) to prevent or combat infection and disease associated with HIV infections, such as AIDS, ARC and HIV-associated cancers.

When the compounds of this invention are administered in combination therapies with other agents, they may be administered sequentially or concurrently to the patient. The additional agents may be administered separately, as part of a multiple dose regimen, from the compounds of this invention. Alternatively, those agents may be part of a single dosage form, mixed together with the compounds of this invention in a single composition. The pharmaceutical compositions according to this invention may comprise a combination of an aspartyl protease inhibitor of this

- 122 -

invention and one or more therapeutic or prophylactic agents.

Although this invention focuses on the use of the compounds disclosed herein for preventing and  
5 treating HIV infection, the compounds of this invention can also be used as inhibitory agents for other viruses which depend on similar aspartyl proteases for obligatory events in their life cycle. These viruses include other AIDS-like diseases caused by  
10 retroviruses, such as simian immunodeficiency viruses, HTLV-I and HTLV-II. In addition, the compounds of this invention may also be used to inhibit other aspartyl proteases, such as renin, pepsin, cymosin, RSV protease, AMV protease, SIV protease and FIV protease,  
15 and in particular, other human aspartyl proteases, including renin, and aspartyl proteases that process endothelin precursors.

Pharmaceutical compositions of this invention comprise any of the compounds of the present invention,  
20 and pharmaceutically acceptable salts thereof, with any pharmaceutically acceptable carrier, adjuvant or vehicle. Pharmaceutically acceptable carriers, adjuvants and vehicles that may be used in the pharmaceutical compositions of this invention include,  
25 but are not limited to, ion exchangers, alumina, aluminum stearate, lecithin, self-emulsifying drug delivery systems (SEDDS) such as d- $\alpha$ -tocopherol polyethyleneglycol 1000 succinate, surfactants used in pharmaceutical dosage forms such as Tweens or other  
30 similar polymeric delivery matrices, serum proteins, such as human serum albumin, polyethyleneglycol polymers such as PEG-400, buffer substances such as phosphates, glycine, sorbic acid, potassium sorbate, partial glyceride mixtures of saturated vegetable fatty

- 123 -

acids, water, salts or electrolytes, such as protamine sulfate, disodium hydrogen phosphate, potassium hydrogen phosphate, sodium chloride, zinc salts, colloidal silica, magnesium trisilicate, polyvinyl pyrrolidone, cellulose-based substances, polyethylene glycol, sodium carboxymethylcellulose, polyacrylates, waxes, polyethylene-polyoxypropylene-block polymers, polyethylene glycol and wool fat. Cyclodextrins such as  $\alpha$ -,  $\beta$ -, and  $\gamma$ -cyclodextrin, or chemically modified derivatives such as hydroxyalkylcyclodextrins, including 2- and 3-hydroxypropyl- $\beta$ -cyclodextrins, or other solublized derivatives may also be advantageously used to enhance delivery of compounds of formula I.

The pharmaceutical compositions of this invention may be administered orally, parenterally, by inhalation spray, topically, rectally, nasally, buccally, vaginally or via an implanted reservoir. We prefer oral administration or administration by injection. The pharmaceutical compositions of this invention may contain any conventional non-toxic pharmaceutically-acceptable carriers, adjuvants or vehicles. In some cases, the pH of the formulation may be adjusted with pharmaceutically acceptable acids, bases or buffers to enhance the stability of the formulated compound or its delivery form. The term parenteral as used herein includes subcutaneous, intracutaneous, intravenous, intramuscular, intra-articular, intrasynovial, intrasternal, intrathecal, intralesional, and intracranial injection or infusion techniques.

The pharmaceutical compositions may be in the form of a sterile injectable preparation, for example, as a sterile injectable aqueous or oleaginous suspension. This suspension may be formulated

- 124 -

according to techniques known in the art using suitable dispersing or wetting agents (such as, for example, Tween 80) and suspending agents. The sterile injectable preparation may also be a sterile injectable solution or suspension in a non-toxic parenterally-acceptable diluent or solvent, for example, as a solution in 1,3-butanediol. Among the acceptable vehicles and solvents that may be employed are mannitol, water, Ringer's solution and isotonic sodium chloride solution. In addition, sterile, fixed oils are conventionally employed as a solvent or suspending medium. For this purpose, any bland fixed oil may be employed including synthetic mono- or diglycerides. Fatty acids, such as oleic acid and its glyceride derivatives are useful in the preparation of injectables, as are natural pharmaceutically-acceptable oils, such as olive oil or castor oil, especially in their polyoxyethylated versions. These oil solutions or suspensions may also contain a long-chain alcohol diluent or dispersant such as carboxymethyl cellulose or similar dispersing agents which are commonly used in the formulation of pharmaceutically acceptable dosage forms such as emulsions and or suspensions. Other commonly used surfactants such as Tweens and Spans and/or other similar emulsifying agents or bioavailability enhancers which are commonly used in the manufacture of pharmaceutically acceptable solid, liquid, or other dosage forms may also be used for the purposes of formulation.

The pharmaceutical compositions of this invention may be orally administered in any orally acceptable dosage form including, but not limited to, hard or soft gelatin capsules, tablets, emulsions and aqueous suspensions, dispersions and solutions. In the

- 125 -

case of tablets for oral use, carriers which are commonly used include lactose and corn starch. Lubricating agents, such as magnesium stearate, are also typically added. For oral administration in a capsule form, useful diluents include lactose and dried corn starch. When aqueous suspensions and/or emulsions are administered orally, the active ingredient may be suspended or dissolved in an oily phase combined with emulsifying and/or suspending agents. If desired, certain sweetening and/or flavoring and/or coloring agents may be added.

The pharmaceutical compositions of this invention may also be administered in the form of suppositories for rectal administration. These compositions can be prepared by mixing a compound of this invention with a suitable non-irritating excipient which is solid at room temperature but liquid at the rectal temperature and therefore will melt in the rectum to release the active components. Such materials include, but are not limited to, cocoa butter, beeswax and polyethylene glycols.

Topical administration of the pharmaceutical compositions of this invention is especially useful when the desired treatment involves areas or organs readily accessible by topical application. For application topically to the skin, the pharmaceutical composition should be formulated with a suitable ointment containing the active components suspended or dissolved in a carrier with suitable emulsifying agents. Carriers for topical administration of the compounds of this invention include, but are not limited to, mineral oil, liquid petroleum, white petroleum, propylene glycol, polyoxyethylene polyoxypropylene compound, emulsifying wax and water.

- 126 -

Alternatively, the pharmaceutical composition can be formulated with a suitable lotion or cream containing the active compound suspended or dissolved in a carrier. Suitable carriers include, but are not  
5 limited to, mineral oil, sorbitan monostearate, polysorbate 60, cetyl esters wax, cetearyl alcohol, 2-octyldodecanol, benzyl alcohol and water. The pharmaceutical compositions of this invention may also be topically applied to the lower intestinal tract by  
10 rectal suppository formulation or in a suitable enema formulation. Topically-transdermal patches are also included in this invention.

The pharmaceutical compositions of this invention may be administered by nasal aerosol or  
15 inhalation. Such compositions are prepared according to techniques well-known in the art of pharmaceutical formulation and may be prepared as solutions in saline, employing benzyl alcohol or other suitable preservatives, absorption promoters to enhance  
20 bioavailability, fluorocarbons, and/or other solubilizing or dispersing agents known in the art.

Dosage levels of between about 0.01 and about 100 mg/kg body weight per day, preferably between about 0.5 and about 75 mg/kg body weight per day of the  
25 active ingredient compound are useful in the prevention and treatment of viral infection, including HIV infection. Typically, the pharmaceutical compositions of this invention will be administered from about 1 to about 5 times per day or alternatively, as a continuous  
30 infusion. Such administration can be used as a chronic or acute therapy. The amount of active ingredient that may be combined with the carrier materials to produce a single dosage form will vary depending upon the host treated and the particular mode of administration. A

- 127 -

typical preparation will contain from about 5% to about 95% active compound (w/w). Preferably, such preparations contain from about 20% to about 80% active compound.

5           Upon improvement of a patient's condition, a maintenance dose of a compound, composition or combination of this invention may be administered, if necessary. Subsequently, the dosage or frequency of administration, or both, may be reduced, as a function  
10 of the symptoms, to a level at which the improved condition is retained when the symptoms have been alleviated to the desired level, treatment should cease. Patients may, however, require intermittent treatment on a long-term basis upon any recurrence of  
15 disease symptoms.

As the skilled artisan will appreciate, lower or higher doses than those recited above may be required. Specific dosage and treatment regimens for any particular patient will depend upon a variety of  
20 factors, including the activity of the specific compound employed, the age, body weight, general health status, sex, diet, time of administration, rate of excretion, drug combination, the severity and course of the infection, the patient's disposition to the  
25 infection and the judgment of the treating physician.

The compounds of this invention are also useful as commercial reagents which effectively bind to aspartyl proteases, particularly HIV aspartyl protease. As commercial reagents, the compounds of this  
30 invention, and their derivatives, may be used to block proteolysis of a target peptide or may be derivatized to bind to a stable resin as a tethered substrate for

- 128 -

affinity chromatography applications. For example, a compound of formula I may be tethered to an affinity column to purify recombinantly produced HIV protease. Derivatization of the compounds of this invention to produce affinity chromatography resins and the methods used to purify proteases using such resins are well known and within the skill of the art. These and other uses which characterize commercial aspartyl protease inhibitors will be evident to those of ordinary skill in the art. (See: Rittenhouse, J. et al. Biochem. Biophys. Res. Commun. 171, p. 60 (1990) and Heimbach, J.C. et al. Ibid 164, p. 955 (1989)).

In order that this invention be more fully understood, the following examples are set forth. These examples are for the purpose of illustration only and are not to be construed as limiting the scope of the invention in any way.

#### General Materials and Methods

All temperatures are recorded in degrees Celsius. Thin layer chromatography (TLC) was carried out using 0.25 mm thick E. Merck silica gel 60 F<sub>254</sub> plates and elution with the indicated solvent system. Detection of the compounds was carried out by treating the plate with an appropriate visualizing agent, such as 10% solution of phosphomolybdic acid in ethanol or a 0.1% solution of ninhydrin in ethanol, followed by heating, and/or by exposure to UV light or iodine vapors when appropriate. Thick layer silica gel chromatography was also carried out using E. Merck 60 F<sub>254</sub> plates ("prep plates") of 0.5, 1.0, or 2.0 mm thickness. Following development of the plate, the

- 129 -

band of silica containing the desired compound was isolated and eluted with an appropriate solvent.

Analytical HPLC was carried out using a Waters Delta Pak, 5  $\mu$ M silica, C18 reversed-phase column, 3.9 mm ID x 15 cm L with a flow rate of 1.5 mL/min using the following table:

Mobile phase: A = 0.1% CF<sub>3</sub>CO<sub>2</sub>H in H<sub>2</sub>O

B = 0.1% CF<sub>3</sub>CO<sub>2</sub>H in CH<sub>3</sub>CN

Gradient: T = 0 min., A (95%), B (5%)

T = 20 min., A (0%), B (100%)

T = 22.5 min., A (0%), B (100%)

Preparative HPLC was also carried out using C<sub>18</sub> reversed-phase media. HPLC retention times were recorded in minutes. NMR spectral data was recorded using a Bruker AMX500, equipped with either a reverse or QNP probe, at 500 MHz, and was taken in the indicated solvent.

We have measured the inhibition constants of each compound against HIV-1 protease using the method described essentially by M.W. Pennington et al., Peptides 1990, Giralt, E. and D. Andreu, Eds., Escom, Leiden, Netherlands (1991); and the method described essentially by Partaledis et al., J. Virol., 69, pp. 5228-35 (1995).

Compounds of invention were tested for their antiviral potency in several virological assays. In the first assay, the compounds were added as a solution in dimethylsulfoxide (DMSO) to a test cell culture of CCRM-CEM cells, a strain of CD4<sup>+</sup> human T-cell lymphoma cells, previously acutely infected with HIV<sub>IIIb</sub> using

- 130 -

standard protocols (see Meek, T. D. et al., "Inhibition of HIV-1 protease in infected T-lymphocytes by synthetic peptide analogues", Nature, 343, p. 90 (1990)).

5               The effect of the compounds on inhibiting the replication of the virus was measured by determining the HIV extracellular p24 antigen concentration using a commercial enzyme immunoassay (obtained from Coulter Corporation, Hialeah, FL).

10               Antiviral activity may also be measured in a separate assay in MT4 cells. Antiviral HIV activity and compound-induced cytotoxicity were measured in parallel by means of a propidium iodide based procedure in the human T-cell lymphotropicvirus transformed cell  
15               line MT4. Aliquots of the test compounds were serially diluted in medium (RPMI 1640, 10% fetal calf serum (FCS), and gentamycin) in 96-well plates (Costar 3598) using a Cetus Pro/Pette. Exponentially growing MT4  
20               cells were harvested and centrifuged at 1000 rpm for 10 minutes in a Jouan centrifuge (model CR 4 12). Cell pellets were resuspended in fresh medium (RPMI 1640, 20% FCS, 20% IL-2, and gentamycin) to a density of  $5 \times 10^5$  cells/ml. Cell aliquots were infected by the  
25               addition of HIV-1 (strain IIIB) diluted to give a viral multiplicity of infection of 100 x TCID<sub>50</sub>. A similar cell aliquot was diluted with medium to provide a mockinfected control. Cell infection was allowed to  
30               proceed for 1 hour at 37 °C in a tissue culture incubator with humidified 5% CO<sub>2</sub> atmosphere. After the 1 hour incubation the virus/cell suspensions were  
diluted 6-fold with fresh medium, and 125 µl of the cell suspension was added to each well of the plate

- 131 -

containing prediluted compound. Plates were then placed in a tissue culture incubator with humidified 5% CO<sub>2</sub> for 5 days. At the end of the incubation period, 27 ul of 5% Nonidet-40 was added to each well of the incubation plate. After thorough mixing with a Costar multitip pipetter, 60 ul of the mixture was transferred to filter-bottomed 96-wellplates. The plates were analyzed in an automated assay instrument (Pandex Screen Machine, Baxter Biotechnology Systems). The assay makes use of a propidium iodide dye to estimate the DNA content of each well. The antiviral effect of a test compound is reported as an IC<sub>50</sub>, i.e. the inhibitory concentration that would produce a 50% decrease in the HIV induced cytopathic effect. This effect is measured by the amount of test compound required to restore 50% of the cell growth of HIV-infected MT-4 cells compared to uninfected MT-4 cell controls.

Depending on the cell type and the desired readout, syncytia formation, reverse-transcriptase (RT) activity, or cytopathic effect as assayed by a dye uptake method may also be used as readouts of antiviral activity. Acad. Sci. USA, vol. 83, pp. 1911-1915 (1986).

Insofar as the compounds of this invention are able to inhibit the replication of the HIV virus in CD<sub>4</sub><sup>+</sup> cells of human lineage, they are of evident clinical utility for the treatment of HIV infection. These tests are predictive of the compounds ability to inhibit HIV protease in vivo.

To a cooled solution (-78 °C) of lactam 1 (0.10g, 0.46mmol) in anhydrous THF (1.0mL) was added  
 5 phosphazene base P4 t-butyl solution (1.0M in hexanes, 0.46mL, 0.46mmol) with stirring. After a 15 min. stirring period, epoxide 2 (0.173g, 0.46mmol) was added in one portion and the reaction was allowed to slowly warm to rt. After 0.5h at rt, 1.0M HCl (10.0mL) was  
 10 added and the solution was diluted with ethyl acetate (60mL). The ethyl acetate was washed with sat. NaHCO<sub>3</sub> (1 x 10mL), brine (1 x 10mL) dried (MgSO<sub>4</sub>), filtered, and evaporated to give a brown foam. The crude acetone  
 15 ide (0.270g, 0.46mmol) was dissolved in isopropanol (10mL) and treated with conc. HCl (3.0mL) at rt. After 2.0h., the solution was adjusted to pH 11 with 3.0N NaOH and extracted with ethyl acetate (3 x 75mL). The ethyl acetate was dried (MgSO<sub>4</sub>) and evaporated to give the crude product which was purified

Dihydro-5(S)-[[[(trifluoromethyl)sulfonyl]oxy]methyl]-3(R)-(phenylmethyl)-3(2H)-furanone (J. Med. Chem., 1994, Vol. 37, No. 21, 3443-51; 1.00 g, 2.96 mmol, 1.1 eq) was added as a solid and the reaction was stirred vigorously for 10 min. and then quenched with several drops of glacial acetic acid. The reaction mixture was evaporated *in vacuo* to a residue and partitioned between ethyl acetate, saturated aqueous brine, and water. After separating the layers, the aqueous layer

was added and reaction allowed to proceed at room temperature for additional 1 h. Purification on silica gel (mixture of diastereomers,  $R_f=0.46$ ,  $0.51$  in 1:3 ethyl acetate/hexane) provided 44 mg (32.2%) of the  
5 TBDMS-protected product. Low resolution MS  $m/e$  1464.6 ( $2M+Na^+$ ),  $m/e$  721.1 ( $M+H^+$ ).

E.

A solution of 40 mg of the silylated product above in 0.3 mL THF was treated with 0.3 mL of 1M TBAF in THF

15 resolution MS  $m/e$  629.3 ( $M+Na^+$ ).

The generic formula I contains almost no fixed structural moiety. In addition, the large number of values for most of the variables, in conjunction with their cascading meanings, renders the scope of the invention for which protection is sought ill-defined and obscure. Consequently, a complete search is precluded for practical and economic reasons.

Guided by the spirit of the application and the inventive concept as disclosed in the descriptive part of the present application the search has been limited to the following case :

X=CO, Y=1-3 undefined optionally subst. ring members

R1 = benzyl

The ring nitrogen atom of generic formula I of claim (I) bears the following substituents -CH<sub>2</sub>-C=O-C or CH<sub>2</sub>-CH(OH)-C
